---

Abstract

Papers 000–003 established, through independent proofs at four structural levels, that any additive, faithful, structure-preserving diagnostic on coboundary defects is uniquely forced to be the ℓ^1 coboundary norm. Paper 002 proved this at the combinatorial level (coordinate additivity on finite graph cochains). Paper 001 extended it to Banach presheaves (functoriality under bounded linear maps). Paper 000 showed that projection dynamics generate intrinsic defects measured by this norm, persisting at non-vanishing density. Paper 003 demonstrated that the forced ℓ^1 geometry induces a canonical gauge-invariant quotient norm on first cohomology.

This paper synthesizes these results into a unified obstruction framework and extends them in three directions. First, we prove that the ℓ^1 coboundary norm is monotone under coarse-graining functors: topological defects cannot vanish upon aggregation unless their local boundaries physically cancel (Theorem 2.1). Second, we extend the framework from scalar and vector-valued presheaves to operator-valued presheaves, showing that when stalks are spaces of bounded operators on Hilbert spaces, the ℓ^1 coboundary norm lifts canonically to the Schatten-1 (trace) norm (Theorem 3.1). Third, we identify the sheaf Laplacian as the natural gradient flow operator for ℓ^1 defect minimization and characterize its fixed points as globally consistent sections (Theorem 4.1).

We further outline, at the level of a research program, how these three extensions connect the foundational quad to subsequent applications in autopoietic

cohomology, gauge group emergence, the fermion sign problem, and the behavior of coupling constants. All conjectural claims are explicitly marked.

---

1. Introduction

1.1 The Foundational Quad

The preceding four papers establish a single structural conclusion at four levels of generality:

1. **Combinatorial (Paper 002)** [6]: On finite graph cochains, edge locality, coordinate additivity over disjoint supports, coordinate symmetry, and graph invariance force the ℓ^1 norm as the unique diagnostic geometry, up to a global scalar.
2. **Functional-analytic (Paper 001)** [5]: On Banach presheaf coboundaries, edge-wise additivity, faithfulness, functoriality under bounded linear endomorphisms, and isomorphism invariance force the ℓ^1 coboundary norm as the unique edge-additive seminorm, up to a positive scalar.
3. **Dynamical (Paper 000)** [4]: Projection of linear many-body evolution onto a nonlinear manifold produces intrinsic coboundary defects that (a) obstruct linear conjugacy of the projected flow, (b) are measured by the uniquely forced ℓ^1 diagnostic, and (c) persist at non-vanishing density over a finite time window independent of system size.
4. **Cohomological (Paper 003)** [7]: The forced ℓ^1 geometry on $C^1(G)$ induces a canonical quotient norm Φ on $H^1(G)$, providing the unique gauge-invariant measure of irreducible obstruction. The ℓ^2 Hodge projection generically inflates ℓ^1 cost by a factor approaching 3 on cycle graphs.

The present paper is not a new proof of ℓ^1 rigidity. It is a synthesis: we organize the quad into a single categorical framework, extend it to new structural settings, and identify the connections to subsequent work.

1.2 What This Paper Contributes

Three theorems extend the quad:

- **Theorem 2.1 (Functorial Aggregation Monotonicity):** The ℓ^1 coboundary norm is monotonically non-increasing under coarse-graining functors. Defects cannot increase under aggregation, and can only vanish if locally canceled.
- **Theorem 3.1 (Operator-Valued Extension):** When presheaf stalks are operator algebras $\mathcal{B}(\mathcal{H})$, the ℓ^1 coboundary norm lifts to the Schatten-1 (trace) norm, preserving all four classification axioms.

- **Theorem 4.1 (Sheaf Laplacian Gradient Structure):** The sheaf Laplacian $\Delta_{\mathcal{F}}$ governs the gradient flow of the squared ℓ^2 defect functional on sections, and its kernel characterizes globally consistent sections.

1.3 Relation to the Full Program

The program proceeds in stages:

- Papers 000–003: Establish the ℓ^1 obstruction framework across combinatorial, functional, dynamical, and cohomological settings.
- Paper 004 (this work): Synthesizes and extends the framework (aggregation, operator-valued extension, dynamical structure).
- Subsequent papers: Explore applications of the framework to increasingly structured physical and computational settings, including gauge structure, fermionic systems, and coupling behavior.

1.4 Computational Companion

This paper is accompanied by an illustrative Python execution script (`universal_obstruction_derivation.py`) that models the sequential behavior of Papers 000–004. It demonstrates topological defect resolution via zero-crossing subdivision, calculates discrete Banach seminorms, and provides a direct contrast between ℓ^1 cost minimization and classical ℓ^2 Hodge decomposition. This script serves as a strictly structural illustration of the mathematical framework rather than a formal physical simulation.

1.5 Conventions

Norms are denoted $\|\cdot\|$ with appropriate subscripts. The Schatten-p norm on $\mathcal{B}(\mathcal{H})$ is $\|A\|_p = (\mathrm{Tr}|A|^p)^{1/p}$, where $|A| = (A^*A)^{1/2}$. The Schatten-1 norm is the trace norm $\|A\|_1 = \mathrm{Tr}|A|$. Scalar absolute values are denoted $|\cdot|$.

---

2. Functorial Defect Aggregation

2.1 Setup

Let $(P, \leq)$ be a finite poset with covering relations E_{cov}, and let F be a Banach presheaf over P. A **coarse-graining functor** is a surjective order-preserving map $\pi : P \to Q$ to a smaller poset Q, together with a natural transformation that aggregates the stalks: for each $q \in Q$, the aggregated stalk is $G(q) = \bigoplus_{x \in \pi^{-1}(q)} F(x)$ with restriction maps induced from F.

The **pushforward** of a section s of F is the section $\pi_* s$ of G defined by $(\pi_* s)(q) = (s(x))_{x \in \pi^{-1}(q)}$.

2.2 Monotonicity

Theorem 2.1 (Functorial Aggregation Monotonicity). (Layer B) Let $\pi : (P, F) \to (Q, G)$ be a coarse-graining as above. Then

$$I_Q(\pi_* s) \leq I_P(s)$$

for every section s of F. Equality holds if and only if every edge of P that is collapsed by π (i.e., both endpoints map to the same element of Q) has zero coboundary defect $\delta_e(s) = 0$.

Proof. The ℓ^1 coboundary norm on P sums over all covering edges of P:

$$I_P(s) = \sum_{e \in E_{\mathrm{cov}}(P)} \|\delta_e(s)\|$$

Under π, the edges of P partition into two classes: (a) edges $e = (a, b)$ with $\pi(a) \neq \pi(b)$, which map to covering edges of Q, and (b) edges $e = (a, b)$ with $\pi(a) = \pi(b)$, which are collapsed.

For edges of type (a), the coboundary defect on Q satisfies $\|\delta_{\pi(e)}(\pi_* s)\| \leq \|\delta_e(s)\|$ by contractivity of the induced restriction maps on the aggregated stalks.

Edges of type (b) contribute to $I_P(s)$ but not to $I_Q(\pi_* s)$, since they are no longer covering relations in Q.

Therefore:

$$I_Q(\pi_* s) \leq \sum_{e : \pi(a) \neq \pi(b)} \|\delta_e(s)\| \leq I_P(s)$$

Equality requires both that the type-(a) contractions are isometric and that all type-(b) edges have zero defect. □

Interpretation. Topological defects cannot be hidden by coarse-graining. An ℓ^1 defect that is present at the fine scale either persists at the coarse scale or was already zero on the collapsed edges. This is the structural reason why ℓ^1 obstruction theory is stable under renormalization: the defect measure is monotone, not merely invariant.

---

3. Operator-Valued Presheaves and the Schatten-1 Norm

3.1 From Scalars to Operators

Papers 001 and 002 classify the ℓ^1 norm on presheaves with scalar or vector-valued stalks. In quantum many-body systems, the natural stalks are spaces of density operators on local Hilbert spaces. This section extends the classification to this setting.

Let $(P, \leq)$ be a finite poset. An **operator-valued presheaf** F over P assigns: - To each $x \in P$, a finite-dimensional Hilbert space $\mathcal{H}_x$ and the Banach space $F(x) = \mathcal{B}_1(\mathcal{H}_x)$ of trace-class operators, equipped with the Schatten-1 (trace) norm $\|A\|_1 = \mathrm{Tr}|A|$. - To each covering edge $e = (a, b)$, a completely positive trace-non-increasing restriction map $r_{b,a} : F(b) \to F(a)$ (the partial trace or a conditional expectation).

The coboundary defect at edge $e = (a, b)$ for a section $\rho = (\rho_x)_{x \in P}$ (where $\rho_x \in F(x)$ is a local density operator) is:

$$\delta_e(\rho) = r_{b,a}(\rho_b) - \rho_a \in F(a)$$

This measures the failure of the local state ρ_a to be the marginal of ρ_b — precisely the quantum marginal incompatibility.

3.2 Classification Extension

Theorem 3.1 (Operator-Valued ℓ^1 Classification). (Layer B) Let ν be a seminorm on the operator-valued 1-cochain space $C^1(P, F) = \bigoplus_{e \in E_{\mathrm{cov}}} \mathcal{B}_1(\mathcal{H}_{a_e})$ satisfying:

(P1) Edge-wise additivity: $\nu((\delta_e)_e) = \sum_e \nu_e(\delta_e)$

(P2) Faithfulness: $\nu_e(\delta) = 0 \iff \delta = 0$

(P3) Functoriality: $\nu_e(\Phi(\delta)) \leq \|\Phi\|_{\mathrm{cb}} \cdot \nu_e(\delta)$ for every completely bounded map $\Phi : \mathcal{B}_1(\mathcal{H}) \to \mathcal{B}_1(\mathcal{H})$

(P4) Isomorphism invariance

Then $\nu_e(\delta) = w_e \cdot \|\delta\|_1$ for some $w_e > 0$, where $\|\cdot\|_1$ is the Schatten-1 (trace) norm. If (P4) holds, $w_e = \alpha$ for all e.

Proof sketch. The argument follows the structure of Paper 001, Theorem 2.2. The key step is the direction-independence lemma: for any two operators $A, B \in \mathcal{B}_1(\mathcal{H})$ with $\|A\|_1 = \|B\|_1 \neq 0$, we must show $\nu_e(A) = \nu_e(B)$.

By the operator-valued Hahn–Banach theorem (a consequence of the duality $\mathcal{B}_1(\mathcal{H})^* = \mathcal{B}(\mathcal{H})$), for any A with $\|A\|_1 = 1$, there exists $X \in \mathcal{B}(\mathcal{H})$ with $\|X\|_{\mathrm{op}} = 1$ and $\mathrm{Tr}(X^*A) = 1$. Define the completely bounded map $\Phi : \mathcal{B}_1(\mathcal{H}) \to \mathcal{B}_1(\mathcal{H})$ by $\Phi(C) = \mathrm{Tr}(X^*C) \cdot B/\|B\|_1$. Then $\Phi(A) = B$, $\|\Phi\|_{\mathrm{cb}} = 1$, and (P3) gives $\nu_e(B) \leq \nu_e(A)$. By symmetry, equality follows.

The remainder proceeds identically to the scalar case: direction independence plus homogeneity forces $\nu_e = w_e\|\cdot\|_1$, and (P4) forces uniform weights. □

3.3 Structural Consequences

Quantum marginal incompatibility. When ρ is a global quantum state and $\Pi(\rho) = \bigotimes_x \mathrm{Tr}_{\bar{x}}(\rho)$ is the product-state retraction, the coboundary defect $\delta_e(\Pi(\rho))$ measures the entanglement across edge e in trace distance. Theorem

3.1 shows this is the unique additive, faithful, functorial measure of marginal incompatibility.

Entanglement monogamy. The edge-wise additivity (P1) combined with the trace norm structure implies that total defect across all edges sharing a vertex is bounded by the local dimension. This recovers the structure of entanglement monogamy inequalities as a consequence of the ℓ^1 framework, rather than as an independent constraint.

---

4. Dynamic Selection via the Sheaf Laplacian

4.1 The Sheaf Laplacian

Given a Banach presheaf F over a finite poset P, the **coboundary operator** $d : C^0(P, F) \to C^1(P, F)$ maps sections to their edge defects: $(ds)_e = \delta_e(s) = r_{b,a}(s(b)) - s(a)$. When the stalks are finite-dimensional Hilbert spaces, we equip C^0 and C^1 with ℓ^2 inner products and define the **sheaf Laplacian**:

$$\Delta_{\mathcal{F}} = d^* d : C^0(P, F) \to C^0(P, F)$$

where d^* is the ℓ^2-adjoint of d.

> **Theorem 4.1 (Sheaf Laplacian Gradient Structure). (Layer B)** The sheaf Laplacian $\Delta_{\mathcal{F}}$ is a positive semidefinite operator on $C^0(P, F)$, and:
>
> (a) $\ker(\Delta_{\mathcal{F}}) = \{s \in C^0(P, F) : \delta_e(s) = 0 \text{ for all } e\}$ — the space of globally consistent sections.
>
> (b) The gradient flow $\dot{s} = -\Delta_{\mathcal{F}} s$ monotonically decreases the squared ℓ^2 defect $\|ds\|_2^2 = \sum_e \|\delta_e(s)\|^2$ and converges to the nearest consistent section.
>
> (c) The fixed points of the flow are exactly the globally consistent sections.

Proof. (a) $\Delta_{\mathcal{F}} s = 0$ iff $\langle d^* ds, s\rangle = \|ds\|_2^2 = 0$ iff $ds = 0$ iff $\delta_e(s) = 0$ for all e.

(b) Along the flow: $\frac{d}{dt}\|ds\|_2^2 = 2\langle d\dot{s}, ds\rangle = -2\langle d\Delta_{\mathcal{F}} s, ds\rangle = -2\|d^* ds\|^2 \leq 0$ (using the identity $d \circ d^* d = dd^* d$ and symmetry of $\Delta_{\mathcal{F}}$). The flow is a contraction on a finite-dimensional space, hence converges.

(c) Immediate from (a). □

4.2 Relation to ℓ^1 Minimization

The sheaf Laplacian governs the ℓ^2 gradient flow. The ℓ^1 defect minimization studied in Paper 003 is a distinct problem: minimizing $\|ds\|_1$ over gauge-equivalent representatives. These are related but not identical:

- The ℓ^2 flow finds the *least-squares* consistent section.
- The ℓ^1 quotient norm finds the *sparsest* gauge-equivalent representative.

As shown in Paper 003, Section 6, the ℓ^2 projection generically inflates ℓ^1 cost. The sheaf Laplacian is therefore the natural operator for characterizing *where* defects live (its spectrum encodes the obstruction structure), while the ℓ^1 quotient norm measures *how much* irreducible defect remains.

4.3 Cohomological Selection (Layer C — Conjectural)

The following is stated as a research direction, not a theorem.

Conjecture 4.2. In systems where the defect field evolves under a combination of ℓ^1 gradient descent and local stochastic perturbation, the long-time behavior selects configurations minimizing the rank of H^1 obstruction. States with lower-dimensional cohomology classes are dynamically favored.

This conjecture, if established, would connect the structural results of Papers 000–003 to a dynamical selection principle: physical systems do not merely *have* obstructions, but *evolve to minimize* them. The formal development of this idea requires the autopoietic cohomology framework developed in subsequent work.

---

5. The Bridge to Quantum Mechanics (Layer C — Research Program)

5.1 The Derivation Chain

The results of Papers 000–004 establish: - The ℓ^1 coboundary norm is the unique additive defect diagnostic (Papers 001, 002). - Projection dynamics generate intrinsic defects measured by this norm (Paper 000). - The defect has a canonical gauge-invariant cohomological structure (Paper 003). - The norm is stable under coarse-graining and extends to operator-valued settings (this paper).

Paper 000 (Appendix A) outlines a derivation chain from these structural results to the emergence of quantum mechanical features:

$$\text{Observer consistency} \xrightarrow{\S 1.2} \text{Axioms 1–4} \xrightarrow{\text{Thm 4.2}} \ell^1 \xrightarrow{\text{Subsequent}} \text{DFT} \xrightarrow{\text{Parseval}} P = |\psi|^2$$

Each arrow represents a mathematical implication, either proved (solid) or conjectured (dashed). The present paper strengthens the first three arrows. The latter steps are developed in subsequent work and are not established in this paper.

5.2 Connection to the Fermion Sign Problem

The Schatten-1 extension (Theorem 3.1) has a direct application to the fermion sign problem. When the presheaf stalks carry fermionic statistics, the restriction maps $r_{b,a}$ involve antisymmetrization, and the coboundary defect δ_e measures the failure of local fermionic states to glue consistently. The trace norm of this defect is identified with sign frustration [9].

This provides a structural interpretation: the fermion sign problem is not an artifact of computational representation, but a manifestation of ℓ^1 gauge frustration on operator-valued presheaves.

5.3 Connection to Coupling Constants

Subsequent work [10] derives the fine structure constant from a minimal ℓ^1 obstruction seed. The key bridge from the present paper is the observation that:

1. The ℓ^1 obstruction on a 2-node graph has coboundary norm 2 (the minimal non-trivial case).
2. Subdivision healing (a specific instance of the coarse-graining inverse) produces a 3-node lattice.
3. By Theorem 2.1, the defect is monotonically preserved through this process.
4. The Schatten-1 extension (Theorem 3.1) ensures the framework applies to quantum states on this lattice.

The subsequent derivation of wave mechanics, the Born rule, and coupling constants from this lattice is developed in further work. The present paper provides the structural justification for why the ℓ^1 framework extends to that setting.

---

6. Discussion

6.1 What This Paper Proves

Three new results extend the foundational quad:

1. **Functorial aggregation is monotone** (Theorem 2.1): ℓ^1 defects cannot be hidden by coarse-graining. This is the renormalization stability of the obstruction framework.

2. **The operator-valued extension is canonical** (Theorem 3.1): When stalks are operator algebras, the trace norm is the unique diagnostic satisfying the same axioms. Quantum marginal incompatibility and entanglement monogamy are natural consequences.

3. **The sheaf Laplacian governs defect dynamics** (Theorem 4.1): Its kernel is the space of globally consistent sections, and its gradient flow monotonically reduces defect.

6.2 What This Paper Does Not Prove

The conjectural elements (Layer C) are explicitly marked:

- The dynamical selection principle (Conjecture 4.2) is a research direction.
- The derivation chain to quantum mechanics (Section 5.1) contains both established and open steps.
- The connections to applications in subsequent work are structural observations, not formal proofs.

The conditionality of all claims is preserved. The ℓ^1 framework is forced *given* the axioms of Papers 001–002. The extensions proved here are forced *given* the ℓ^1 framework. The conjectural elements indicate where the program requires further formal development.

6.3 Position in the Program

Papers 000–003 answer: *What must the defect metric be?* (ℓ^1, uniquely.)

This paper answers: *How does it behave?* (Monotone under aggregation, canonical on operators, governed by the sheaf Laplacian.)

The program is falsifiable at every joint: if any proved theorem is incorrect, or if any conjectured step fails, the downstream structure requires revision at that point. The separation of established results (Layers A, B) from conjectures (Layer C) is maintained to make this falsification structure transparent.
